Practice Gaps in Pediatric Acne Treatment

A practice gap is the gap between what the medical professional is doing or accomplishing in clinical practice (current reality) compared with what is or should be achieved in practice based on the best available evidence or professional knowledge (1). Practice gaps are a problem in acne management. Though one of the most common skin conditions in children and adolescents, there is tremendous variation in acne treatment among healthcare professionals.

For example, while topical retinoids are extremely beneficial in the treatment of mild-to-moderate acne, and are important in maintenance therapy of all types of acne, they are inconsistently prescribed, especially by non-dermatologists (2). A retrospective review of the National Ambulatory Medical Care Survey (NAMCAS) found that amongst teenagers, topical retinoids were prescribed at 38.3% of dermatology visits but only at 15.7% of primary care visits (3). In patients, topical retinoids were prescribed at 32.6% of dermatology visits but only 10.5% of primary care visits (3). In addition, a NAMCAS review reported significant use of topical antibiotic monotherapy, a practice that may lead to antimicrobial resistance (4, 5). Primary care physicians also more commonly utilize oral antibiotics, without concurrent topical retinoids, a practice of use different than dermatologists (3).

Interventions targeting providers can help decrease practice gaps (6, 7), and adults have been shown to learn best in case-based, interactive educational sessions, as opposed to traditional didactic formats (6). In our study, we employ a case-based educational intervention targeting pediatrician’s knowledge of the 2013 evidence-based guidelines for the treatment of pediatric acne published by the American Acne and Rosacea Society (AARS). We surveyed both baseline knowledge and immediate knowledge gain after a 1 hour-case based interactive learning session. We hypothesized that after the intervention, providers would demonstrate increased ability to choose acne treatments in concordance with the evidence-based guidelines.

Methods and Case-Based Questions

Participants were recruited at 3 educational conferences throughout the United States. They rated their knowledge of and confidence in prescribing according to the AARS guidelines on a 5-point scale. They also answered 5 case-based questions assessing the next best step for a variety of patients with acne, both before and after the educational intervention. Responses were evaluated for being consistent with guidelines recommendations or not consistent. The five case-based questions assessing the next best step for a variety of patients with acne included:

1. A 16-year-old girl with 25 closed comedones on her face and a few inflammatory lesions (mild acne).
2. A 14-year-old boy with 20 closed comedones on the forehead and no inflammatory lesions (mild acne).
3. A 14-year-old boy with 25 inflammatory papules and 30 open and closed comedones on the face (mild to moderate acne).
4. A 14-year-old boy with a moderate amount of inflammatory papules and pusules on the forehead, cheek, chin, chest, and back (moderate acne).
5. A 15-year-old boy with extensive inflammatory lesions and a small amount of diffuse scarring on his face (severe acne). He has been using DTC salicylic acid wash.

Demographics

174 providers participated. We collected the following data: % (number) 

Specialty: Pediatricians 97% (169). Pediatric Residents 10% (13), Nurse Practitioners 5% (7), Physician Assistants 4% (5), Family Practitioners 1% (1).

Gender: Female 64% (86), Male 36% (48).

Location: Suburban 58% (77); Urban 35% (47); Rural 7% (10).

Practice Setting: Pediatric Practice 72%; Academic Practice 4%; General Practice 16%; Pediatric Specialty Group 16%; Hospital 5%; Other 1% (2). 

Years in Practice: 0 years 15% (25); 1-10 years 12% (20), 10-20 years 23% (31); >20 years 45% (65).

Pre-Intervention Guideline Knowledge

Discussion

The AARS guidelines on pediatric acne management have been disseminated with mixed impact on pediatric care providers. pre-intervention, almost 15% of participating providers reported "poor" knowledge of and confidence in prescribing according to the guidelines. These trends illustrate the importance of targeted interventions to improve provider knowledge of and confidence in using evidence-based guidelines.

Post-intervention, significantly more providers chose a treatment in accordance with evidence-based guidelines for pediatric patients with moderate and severe acne, and no providers chose inappropriate antibiotic therapy. These results demonstrate that a learning intervention targeting practice gaps can have a significant impact on provider knowledge.

Study limitations: The prescribing behavior of pediatric providers caring for actual patients was not observed; instead, behavior was assessed using case-based scenarios. Also, there is a lack of long term follow-up to evaluate retention of knowledge gained from the intervention.
